

## The "Two-Pass" Approach

Wednesday, December 31, 2025

2:23 AM

### 1. The core conflict

A standard Binary Search has one goal: find ANY match.

- When it sees  $\text{nums}[\text{mid}] == \text{target}$ , it returns  $\text{mid}$  immediately.

- The failure: If the array is  $[8, 8, 8]$ , standard BS returns index 1. It doesn't know if indices 0 (or 2) are also 8. We can't scan linearly (while...) because that degrades to  $O(n)$  in the worst case (e.g., all elements are identical).

### 2. The Solution

To crack this, we modify the behavior only when a match is found. Instead of stopping, we force the search to continue in a specific condition.

We run Binary Search twice:

1. Search A (Left Bias): finds the start index.

2. Search B (Right Bias): finds the end index.

### 3. Logic Breakdown

Here is exactly how the logic changes for the two searches.

Search A : finding the first Position (Start)

- Goal: find the target furthest to the left.

- Logic: when  $\text{nums}[\text{mid}] == \text{target}$ :

- "I found a target at mid. This might be the first one, (or) maybe there's another one before it."

- Action:

- 1. Save mid as a potential answer.

- 2. Reject the Right side. Move  $\text{end} = \text{mid} - 1$

- 3. Continue searching the left half.

Search B : Finding the last Position (End)

- Goal: find the target furthest to the right.

- Logic: when  $\text{nums}[\text{mid}] == \text{target}$ :

- "I found a target at mid. This might be the last one, (or) maybe there's another one after it."

- Action:

- 1. Save mid as a potential answer.

- 2. Reject the Left side. Move  $\text{start} = \text{mid} + 1$

- 3. Continue searching the Right half.

### 4. Find Algorithm Steps

1. Check Edge Case: If the list is empty, return  $[-1, -1]$ .

2. Run Left-Bias Search: Get  $\text{start\_index}$ .

- Optimization: If  $\text{start\_index}$  is  $-1$  (target not found), return  $[-1, -1]$  immediately. No need to run the second search.

3. Run Right-Bias Search: Get  $\text{end\_index}$

4. Return:  $[\text{start\_index}, \text{end\_index}]$

### 5. Complexity Analysis

- Time:  $O(\log n) + O(\log n) \rightarrow O(\log n)$

We perform two independent binary searches.

- Space:  $O(1)$

We only store variables ( $\text{start}$ ,  $\text{end}$ ,  $\text{mid}$ ,  $\text{result}$ ).

**SORTED ARRAYS GROUP DUPLICATES TOGETHER.**

If you find one, the others are immediate neighbors.
